Description

TECHNICAL FIELD

[0001] The present invention relates to novel benzofuran derivatives, their production, and pharmaceutical compositions containing them. More specifically, it relates to compounds having excellent pharmacological activities such as a neurotrophic factor-like activity, a neurotrophic factor activity-enhancing activity, a neurodegeneration inhibitory activity, a β -amyloid toxicity inhibitory activity and the like, and are effective as prophylactic and therapeutic drugs for neurodegenerative diseases and the like.

BACKGROUND ART

[0002] Neurodegenerative diseases are progressive diseases to cause destructive injuries such as the nerve cell death. As principal neurodegenerative diseases, there have been known central nervous diseases such as Alzheimer's disease, Parkinson's disease, amyotrophic lateral sclerosis (ALS), Huntington's disease, and the like and peripheral neuropathies such as typically diabetic neuropathy. Many of them relate to aging and, in fact, the onset increases with aging, whereas there is a case in which the onset begins even at a middle age and further at a younger age.

[0003] As a result of studies on the structure and function of brains, the roles of neurotransmitters and neurotrophic factors and so on have been gradually elucidated, but many parts of the causes of neurodegeneration are still unknown. Only for Parkinson's disease, the relation between it and a specific neurotransmitter, namely dopamine, has been clarified, whereby L-dopa that is the precursor of dopamine has been used as a drug for reducing the nervous symptoms and for recovering the function. However, L-dopa does not suppress the progress of neurodegeneration, and the effect of L-dopa is gradually lost with a progress of the disease condition, namely the degeneration and deficiency of dopamine-based nerve cells. Also, Alzheimer's disease is a disease that is caused by the degeneration and deficiency of a variety of nerve cells such as acetylcholine-based nerve cells, monoamine-based nerve cells, and the like and, as for the drugs therefor, cholinesterase inhibitors have been marketed or under development. Nevertheless, like L-dopa for Parkinson's disease, they are still within the region of symptomatic therapy to improve the nerve symptoms temporarily.

[0004] Thus, there has not been reported up to the present time any drug that protects nerve cells from the toxicity of factors causing cell death thereby suppressing the progress of neurodegenerative diseases including Alzheimer's disease and Parkinson's disease.

[0005] Moreover, it is said that the cell death in neurodegenerative diseases is caused by the toxicity of the factors that are intrinsic to the respective diseases and, for example, in Alzheimer's disease, the endogenous β -amyloid is considered to be a factor to cause the cell death. β -Amyloid is a protein constituting the senile plaque, which is a neuropathological characteristic to be seen in brain of a patient suffering from Alzheimer's disease, and is composed of 40 to 43 amino acids. It has been elucidated that the addition of this β -amyloid to a primary culture of hippocampus nerve cell causes nerve cell death [Science, Vol. 245, pp. 417-420 (1989)] and, also, it has been shown that the coagulation of β -amyloid is indispensable for the expression of its toxicity and the like [Neurobiology of Aging, Vol. 13, pp. 587-590 (1992) and Journal of Molecular Biology, Vol. 218, pp. 149-163 (1991)]. For toxicity expression mechanism of β -amyloid, there have been conceived that 1) β -amyloid forms an ion channel to allow an inflow of calcium ions, 2) β -amyloid accelerates generation of free radicals, 3) β -amyloid activates tau protein kinase I (TPK-I) to promote the phosphorylation of tau, 4) β -amyloid activates the microglia, from which the neurotoxin is secreted, and the like.

[0006] Recently, it has been elucidated that neurotrophic factors such as IGF-1 (insulin-like growth factor), NGF (nerve growth factor), and the like inhibit the apoptosis of nerve cells by β -amyloid and the like, and that, as the mechanism thereof, inhibition of TPK-I/GSK-3 β (glycogen synthetase kinase 3) by activation of PI-3 kinase is concerned in the apoptosis inhibition [Journal of Neuroscience (J. Neurosci.), Vol. 11, pp. 2552-2563 (1991), Science, Vol. 267, pp. 2003-2005 (1995), and The Journal of Biological Chemistry (J. Biol. Chem.), Vol. 272, 154-161 (1997)]. When PI-3 kinase is inhibited by β -amyloid and TPK-I/GSK-3 β is activated, pyruvate dehydrogenase (PDH) is inhibited, thereby affecting the synthetic reaction system of acetylcholine to lower the content of acetylcholine. This fact agrees with an observation that the content of acetylcholine is lowered in brain of a patient suffering from Alzheimer's disease. On the contrary, it is expected that the activation of PI-3 kinase results in not only the prevention of nerve cell death but also an increase in the content of acetylcholine in brain, thereby improving the nerve symptoms. In addition, it can be expected that inhibition of TPK-I/GSK-3 β increases the intracerebral glucose utilization, which is lowered in Alzheimer's disease [The Journal of Biological Chemistry (J. Biol. Chem.), Vol. 269, 3568-3573 (1994) and Endocrinology, Vol. 125, pp. 314-320 (1989)].

The thus-obtained compound (1a) can be isolated from the reaction mixture and purified according to a known means such as trans-solubilization, concentration, solvent extraction, fractional distillation, crystallization, recrystallization, chromatography, or the like.

[0245] In the case where compound (1a) exists as configurational isomers, diastereomers, conformers, or the like, each of them can be isolated, as desired, by the above-mentioned separation and purification means. Experimental Example 1a

[0531] Cytoprotection in human neuroblastoma SK-N-SH cells against a PI-3-kinase inhibitor, LY-294002

[0532] (Materials for Experiments and Experimental Procedures)

a) Materials for Experiments

[0533] Human neuroblastoma SK-N-SH cells were purchased from American Type Cell Culture (ATCC). DMEM/F-12 culture medium and potassium/magnesium-free phosphate buffer saline (PBS(-)) were purchased from Nikken Biomedical Co., Ltd., N2 additives and EDTA solution from GIBCO BRL Company, fetal bovine serum (FCS) and a mixed solution of penicillin (5000U/ml) and streptomycin (5 mg/ml) from BioWhittaker Inc., Alamarblue™ reagent from Wako Pure Chemical Industries Ltd., culture flasks from Falcon Company, collagen-coated 96-well multi-plates from Iwaki Glass Co., Ltd., and LY-294002 from Alexis Biochemicals, respectively. As for other reagents, commercially available guaranteed reagents were used.

b) Experimental Procedures

(1) Cultivation of SK-N-SH cells

[0534] By using DMEM/F-12 culture medium which contains 5% FCS, 0.5% N2, 10 mM HEPES, and a 1% mixed solution of penicillin (5000U/ml) and streptomycin (5 mg/ml), SK-N-SH cells were subcultured in a carbon dioxide incubator under a mixed gas atmosphere consisting of 10% carbon dioxide and 90% air. After being cultivated to a sub-confluent stage, the cells were detached by a PBS(-) solution containing 2.5 mM EDTA and seeded onto collagen-coated 96-well multi-plates in the proportion of 1.0×10^4 cells/100 μ l/well. After cultivation for 24 hours, the cells thus prepared were used for the cytoprotection assay.

(2) Action to protect the nerve cells from LY-294002- induced cytotoxicity

[0535] There was removed 80 μ l of the culture medium of SK-N-SH cells that was cultivated as described above on 96-wells, collagen-coated, multi-plates and thereto were added at the same time 40 μ l each of LY-294002 of the final concentrations of 30 μ M and each test compound the final concentrations of that was adjusted to be 1.0 μ M, to initiate the cytotoxicity test. Hereupon, each test compound was used after adjusting the concentration to be 10 mM with dimethyl sulfoxide and LY-294002 was used after adjusting the concentration to be 100 mM with dimethyl sulfoxide, each of which was diluted prior to its use in the test.

(3) Evaluation of the survival activity of cells

[0536] The survival activity of nerve cells that were still living one day after initiation of the cytotoxicity test was determined by the activity of the cells to reduce the Alamarblue™ reagent as an index. There was removed 20 μ l of the culture medium and 20 μ l of Alamarblue™ reagent was added. The amount of Alamarblue™ reagent reduced by the cells over the period of 4 hours was colorimetrically determined (measurement wave length: 570 nm; reference wave length: 600 nm) By using a plate reader (WAKO SPECTRAMAX 250 Microplate Reader). Cytoprotection activity was calculated according to the following equation.

$$\text{Cytoprotection activity of each compound} = (A - B)/(C - B) \times 100 (\%)$$

A: The survival activity of the group consisting of a test compound and LY-294002 added

B: The survival activity of the group consisting of LY-294002 added

C: The survival activity of the control group

(Results)

[0537] The cytoprotection activity of each compound was obtained By using at least 4 wells for every dose of a test compound. The results are shown below.

Table 3

Compound of Example	Cytoprotection Activity (%)
6a	28.2
14a	26.6

[0538] These results reveal that, like neurotrophic factors, compounds (1a) and compounds (1a') possess cytoprotection against the cytotoxicity by LY-294002, which is a PI-3 kinase inhibitor and causes nerve degeneration, thereby suppressing the nerve degeneration.

Experimental Example 1b

[0762] Cytoprotection in human neuroblastoma SK-N-SH cells against a PI-3-kinase inhibitor, LY-294002

[0763] (Materials for Experiments and Experimental Procedures)

a) Materials for Experiments

[0764] Human neuroblastoma SK-N-SH cells were purchased from American Type Cell Culture (ATCC). DMEM/F-12 culture medium and potassium/magnesium-free phosphate buffer saline (PBS(-)) were purchased from Nikken

Biomedical Co., Ltd., N2 additives and EDTA solution from GIBCO BRL Company, fetal bovine serum (FCS) and a mixed solution of penicillin (5000U/ml) and streptomycin (5 mg/ml) from BioWhittaker Inc., Alamarblue™ reagent from Wako Pure Chemical Industries Ltd., culture flasks from Falcon Company, collagen-coated 96-well multi-plates from Iwaki Glass Co., Ltd., and LY-294002 from Alexis Biochemicals, respectively. As for other reagents, commercially available guaranteed reagents were used.

b) Experimental Procedures

(1) Cultivation of SK-N-SH cells

[0765] By using DMEM/F-12 culture medium which contains 5% FCS, 0.5% N2, 10 mM HEPES, and a 1% mixed solution of penicillin (5000U/ml) and streptomycin (5 mg/ml), SK-N-SH cells were subcultured in a carbon dioxide incubator under a mixed gas atmosphere consisting of 10% carbon dioxide and 90% air. After being cultivated to a sub-confluent stage, the cells were detached by a PBS(-) solution containing 2.5 mM EDTA and seeded onto collagen-coated 96-well multi-plates in the proportion of 1.0×10^4 cells/100 μ l/well. After cultivation for 24 hours, the cells thus prepared were used for the cytoprotection assay.

(2) An action to protect the nerve cells from LY-294002-induced cytotoxicity

[0766] There was removed 80 μ l of the culture medium of SK-N-SH cells that was cultivated as described above on 96-wells, collagen-coated, multi-plates and thereto were added at the same time 40 μ l each of LY-294002 of the final concentrations of 30 μ M and each test compound the final concentrations of that was adjusted to be 1.0 μ M, to initiate the cytotoxicity assay. Hereupon, each test compound was used after adjusting the concentration to be 10 mM with dimethyl sulfoxide and LY-294002 was used after adjusting the concentration to be 100 mM with dimethyl sulfoxide, each of which was diluted prior to its use in the test.

(3) Evaluation of the survival activity of cells

[0767] The survival activity of nerve cells that were still living one day after initiation of the cytotoxicity test was determined by the activity of the cells to reduce the Alamarblue™ reagent as an index. There was removed 20 μ l of the culture medium and 20 μ l of Alamarblue™ reagent was added. The amount of Alamarblue™ reagent reduced by the cells over the period of 4 hours was colorimetrically determined (measurement wave length: 570 nm; reference wave length: 600 nm) By using a plate reader (WAKO SPECTRAMAX 250 Microplate Reader). Cytoprotection activity was calculated according to the following equation.

$$\text{Cytoprotection activity of each compound} = (A - B)/(C - B) \times 100 (\%)$$

A: The survival activity of the group consisting of a test compound and LY-294002 added

B: The survival activity of the group consisting of LY-294002 added

C: The survival activity of the control group

(Results)

[0768] The cytoprotection activity of each compound was obtained By using at least 4 wells for every dose of a test compound. The results are shown below.

Table 9

Compound of Example	Cytoprotection Activity (%)
20b	12.6
22b	12.8
24b	16.4
45b	20.6
52b	16.4

[0769] These results reveal that, like neurotrophic factors, compounds (Ib) possess cytoprotection against the cytotoxicity by LY-294002, which is a PI-3 kinase inhibitor and causes nerve degeneration, thereby suppressing the nerve degeneration.

INDUSTRIAL UTILITY

[0770] Compounds (Ia), (Ia'), and (Ib) of the present invention or salts or prodrugs thereof possess an excellent action to inhibit the nerve degeneration and the like as well as an excellent brain penetrability and are low in the toxicity, thereby being useful as prophylactic/therapeutic drugs for nerve degenerative diseases and the like.
